

# Field CHA-017

90 acres in Champaign County, Illinois. What the satellite record shows for the 2026 season.

Prepared Oct 6, 2026  
Imagery through Oct 2, 2026  
Villicus

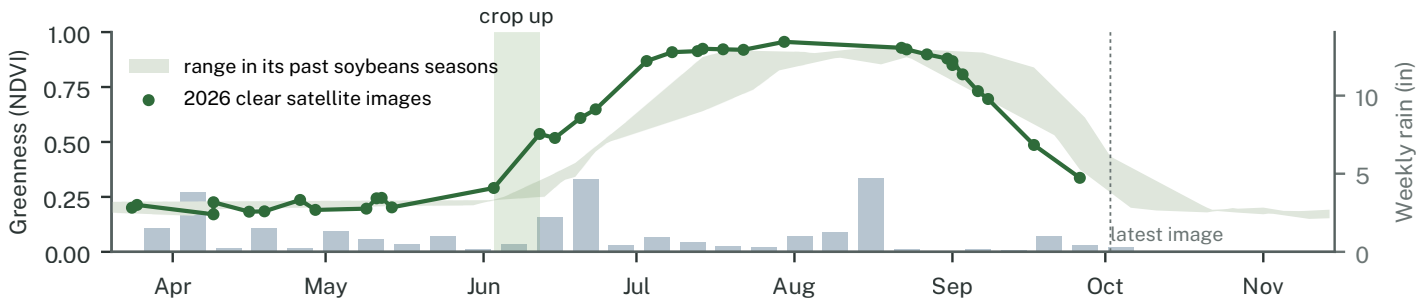

USDA NAIP aerial photo, 2023. Field boundary in yellow.

|                        |                                                                                                              |
|------------------------|--------------------------------------------------------------------------------------------------------------|
| 2026 crop              | Soybeans (high confidence)                                                                                   |
| Crop came up           | between Jun 3 and Jun 12, so likely planted May 20 to Jun 5                                                  |
| Harvest                | crop had dried down by Sep 26; harvest not yet seen as of Sep 26                                             |
| After the 2025 harvest | Tilled (fall); residue dropped between Oct 16, 2025 and Oct 31, 2025                                         |
| Winter 2025-26         | No cover crop seen (8 clear winter images, all bare)                                                         |
| Season greenness       | 1st greenest of its 4 soybeans seasons since 2020; 76th percentile of 1,753 Champaign County soybeans fields |

Crop by year: USDA Cropland Data Layer 2019-2025; 2026 from our model.

## The 2026 season

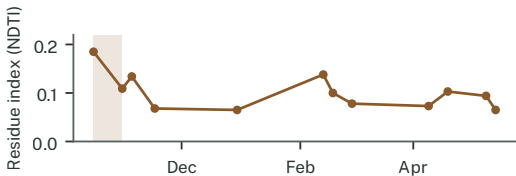

## After the 2025 harvest

Oct 16, 2025, Sentinel-2 (before)

Oct 31, 2025, Sentinel-2 (after)

## Worth a look

Nothing inside the boundary stood out in the last four seasons: no persistent low spots, no hot spots, no change in land use.

This field is in soybeans for 2026, and the crop was up by Jun 12. Harvest has not shown up in the imagery yet; the latest clear image is from Sep 26. Through the summer it stayed ahead of most soybeans fields in the county (76th percentile on greenness), which tracks crop vigor but is not a yield estimate. It was tilled after last year's harvest (between Oct 16, 2025 and Oct 31, 2025), and nothing inside the boundary stood out as a problem area.

Evidence. Dates above rest on these satellite scenes: Oct 16 2025, tillage (S2C T16TDK orbit 126); Oct 31 2025, tillage (S2B T16TDK orbit 126); Jun 3 2026, crop up (S2C T16TDK orbit 126); Jun 12 2026, crop up (Landsat 9 path/row 023032); Jul 30 2026, peak (Landsat 9 path/row 023032); Sep 17 2026, dry-down (Landsat 8 path/row 022032); Sep 26 2026, dry-down, harvest (S2B T16TDK orbit 126). The chart and winter checks use 81 clear images from Aug 2025 on, all listed in the field record file.

How it was made. Greenness is NDVI and the residue index is NDTI, averaged 10 m inside the boundary (USDA NASS Crop Sequence Boundaries). Crop up is when greenness first passed 0.30; planting is estimated 1-2 weeks earlier. Hot spots use Landsat 8/9 surface temperature. Season greenness tracks crop vigor and is not a yield estimate.
